

Incident report analysis

Instructions

As you continue through this course, you may use this template to record your findings after completing an activity or to take notes on what you've learned about a specific tool or concept. You can also use this chart as a way to practice applying the NIST framework to different situations you encounter.

Summary	The multimedia company recently experienced a DoS attack which compromised the internal network for 2 hours. The organization's network services suddenly stopped and the normal internal network cannot even access the network resources like local routers,DHCP or DNS servers,e.t.c. The reason behind the DoS attack is due to the incoming flood of ICMP packets. We believe that this is done by a threat actor whose intention is to make the organization's network services unavailable to disrupt the business continuity.
Identify	The company's cybersecurity team analyzed the organization's network traffic through network analysis tools to identify the security flaws. The team found that a malicious actor had sent a flood of ICMP pings into the company's network through an unconfigured firewall. The unconfigured firewall is the security gap that led to this attack. This vulnerability allowed the malicious attacker to overwhelm the company's network through a denial of service (DoS) attack.
Protect	The network security team implemented a new firewall rule to limit the rate of incoming ICMP packets. We will implement an IDS/IPS system to filter out ICMP traffic based on the suspicious characteristics.
Detect	To detect any new flood attacks, the network security team will use a network monitoring software to detect abnormal traffic patterns rather than following a

	predefined set of rules. The implementation of IDS/IPS to filter out the ICMP traffic or any traffic based on the suspicious characteristic and source IP address verification on the firewall to check for spoofed IP addresses on incoming ICMP packets
Respond	When the attack has been reported, the incident management team responds by blocking incoming ICMP packets, stopping all non-critical network services offline, and restoring critical network services. The security team investigated the security events and took security measures to address the security event. We will inform the security team to maintain the firewall rules and other security measures to be taken to reduce the attack surface. Management will also need to inform law enforcement and other organizations as required by local laws.
Recover	The security team successfully mitigated a 2 hours of DoS attack that disrupted the internal network . The security team recovers the critical network services back to normal operations and informs the network security team to configure the firewall rules to limit the rate of ICMP packets within the network traffic

Reflections/Notes:

This incident highlighted the importance of firewall configuration as a first line of defense. A misconfigured firewall can render all other security controls ineffective. Regular firewall audits should be scheduled to prevent similar vulnerabilities. Additionally, having an IDS/IPS in place before an attack occurs would significantly reduce response time.
